

# nBLM system: data processing

*Irena Dolenc Kittelmann*

ESS

*(BLM System Lead)*

- nBLM
  - Reminder
- FW functionality – block diagram
  - Neutron detection algo
  - Protection algo
- nBLM DAQ first test (Linac4)
  - Preliminary results

# nBLM: reminder

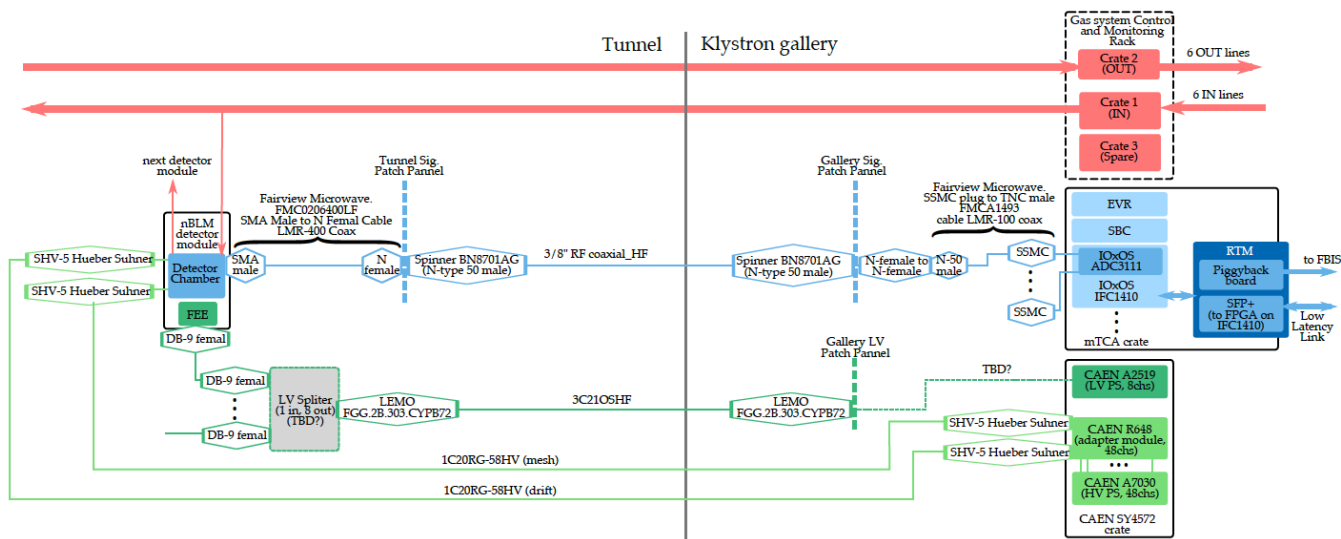

## FEE & detectors

- Housed in a detector module together with the detector chamber and HV mezzanine card

## BEE

- IOxOS IFC1410
- IOxOS ADC3111 FMC digitizer
  - 250MS/s, DC coupled, 16-bit, +/-0.5V
- FBIS interface:
  - RTM with piggyback card
  - IOxOS FMC, DIO3118 – temporary solution for test purposes
- Low Latency Link: SFP+ on RTM
- Alternative to IFC1410
  - Struck SIS8300-KU + SIS8900 RTM
  - 125MS/s, +/-1V, 16bit, DC coupled

## nBLM mode of operation:

- Measurement: neutron counts
- The system is operating in two modes, transition is automatic on the FW level.
- **Counting mode:** individual neutron signals are counted
- **Current mode:** the rate of incoming neutrons is too high to be able to distinguish between 2 individual neutron signals
  - Events pile up
  - Number of neutrons estimated through charge.

## Typical neutron signal

- The characteristics depend on detector properties/settings (drift length, applied voltage/gain) - settings not finalized.
- Typical numbers:
  - 30-50ns rise time
  - 100-200ns signal length
  - Amplitude:
    - nBLM-S: ~ constant (~100mV)
    - nBLM-F: continuous (maximum value 500mV - ADC saturation)
- **Note:** the nBLM signals are negative.

# Processing & monitoring requirements

- System able to run stand alone independent of linac operation.
- Each AMC able to process up to 8 detector channels simultaneously.
- Signal samples at minimum 2MS/s
- All BLM systems follow the same approach where applicable.
- Monitoring data available either:
  - On demand – DoD data
  - Periodically (@max 14Hz) – periodic data

# Processing & monitoring requirements

## DoD data:

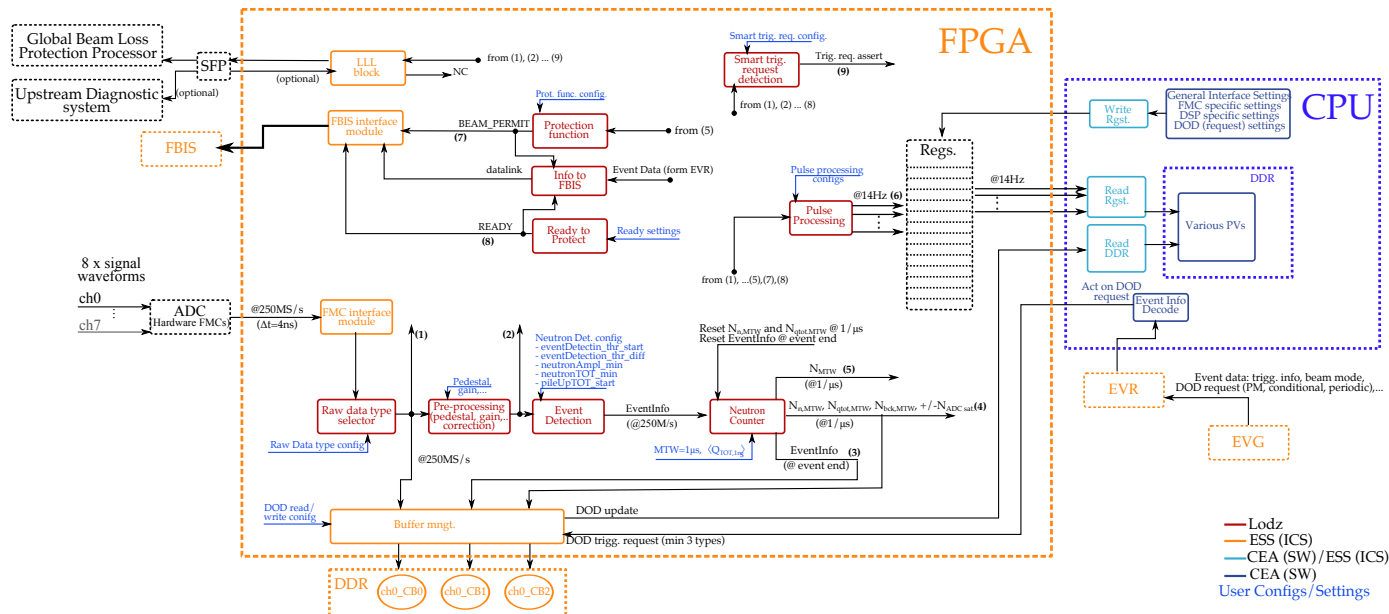

- Continuously buffered and accessible for retrieval without stopping the buffering.
- Min 3 consecutive pulse periods of raw data and 100 pulse periods of processed data available for retrieval on demand (pulse period =  $1/(14 \text{ Hz})$ ).
- Configurable post- and pre-trigger
- In case of raw data (processed data), the post and pre-trigger can be at minimum set to select from 2 (99) pulse periods before to 2 (99) pulse periods after the tagged pulse period – together minimum 3 (100) consecutive pulse periods per request.
- 3 different types of DoD trigger requests at min:
  - Post-mortem
  - Periodic (fx. 1/day)
  - Conditional (certain conditions reached in one of the systems)

# Relaxed requirements on DoD data

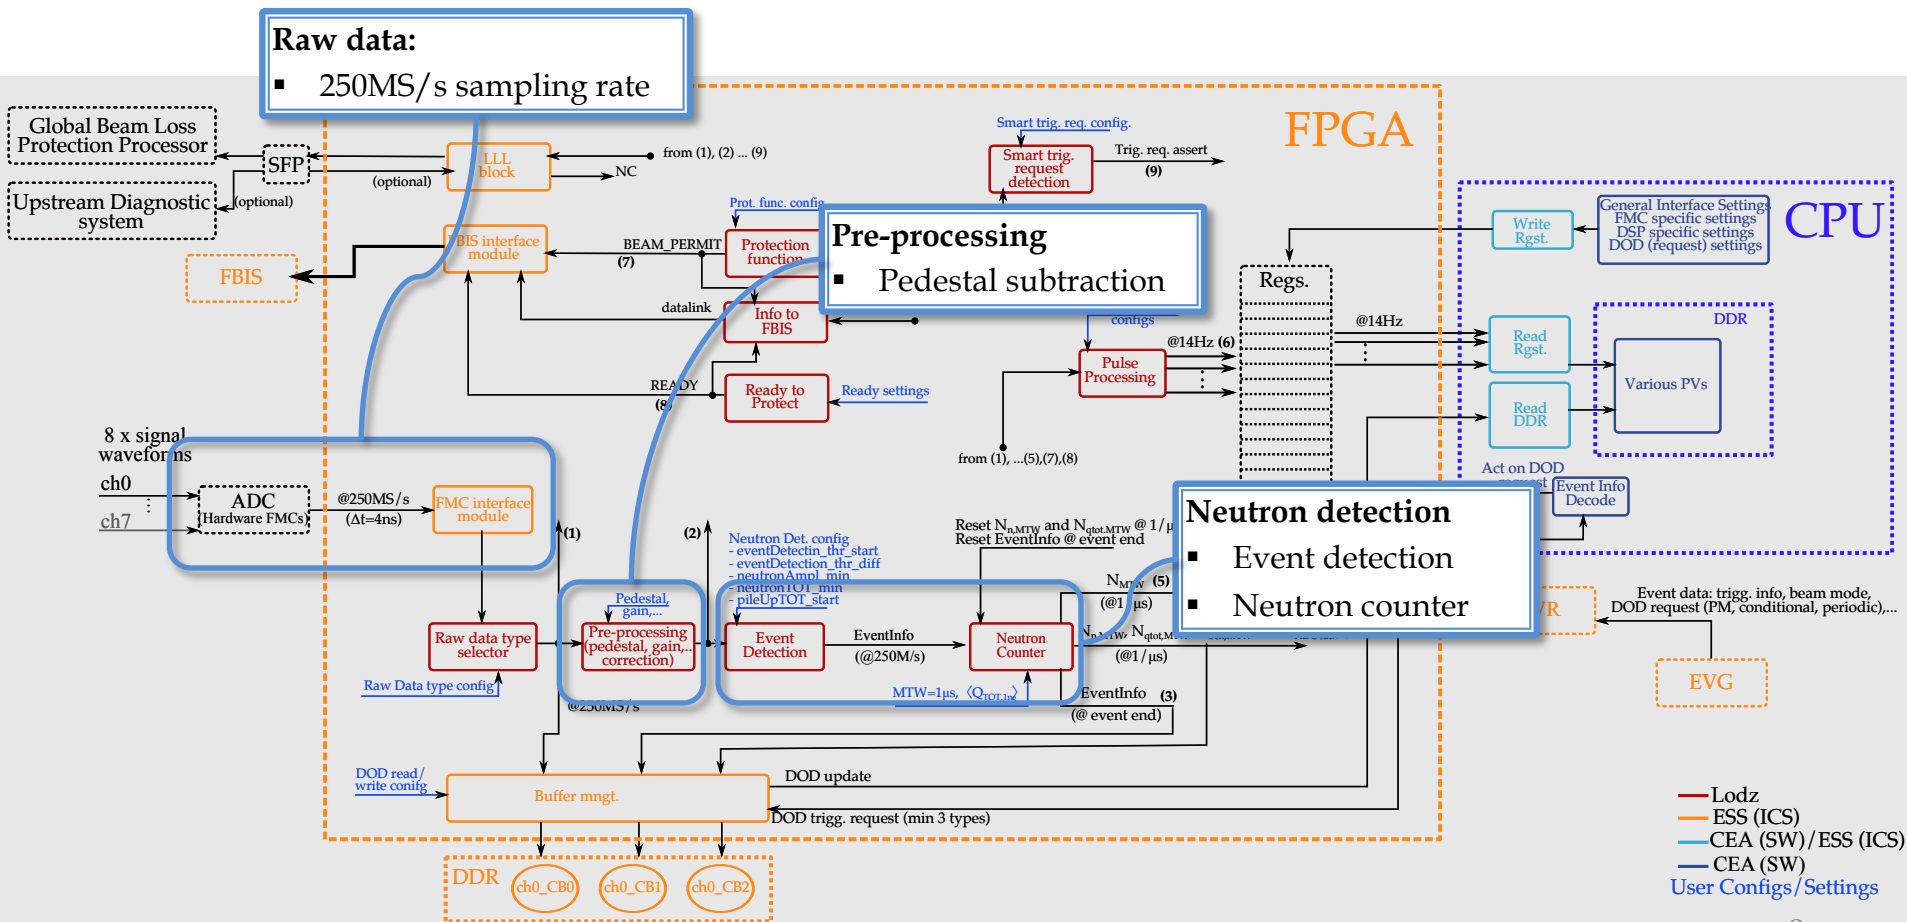

- Requirement on raw data buffering – challenge
- Requirements on nBLM DoD relaxed temporarily
- **Relaxed version**
  - Data available for retrieval on each DoD request in relaxed version:
    - Limited amount of raw data
    - Minimum 100 pulse periods of neutron counts buffer (CB2) for minimum 6 channels.
  - Limited amount of raw data, either:
    - Minimum 2 chs with continuously sampled – minimum 3 consecutive pulse periods (with pre- and post-trigger option)
    - Minimum 6 chs sampled only in a certain time window inside the pulse period:
      - minimum size of sampling time window: 9ms
      - Minimum 3 consecutive sampling time windows available on demand (with pre- and post-trigger).

# nBLM FW functionality

- nBLM block diagram:
  - FPGA based data processing, connection to SW
  - Here: short overview of the functionality
  - Details in nBLM CDR supporting material (I.D.Kittelmann, “Requirements and technical specifications – ESS nBLM system”)
- Implementation details:
  - Talk by G. Jablonski
  - More in related reports (part of the nBLM CDR supporting material)

# nBLM FW functionality

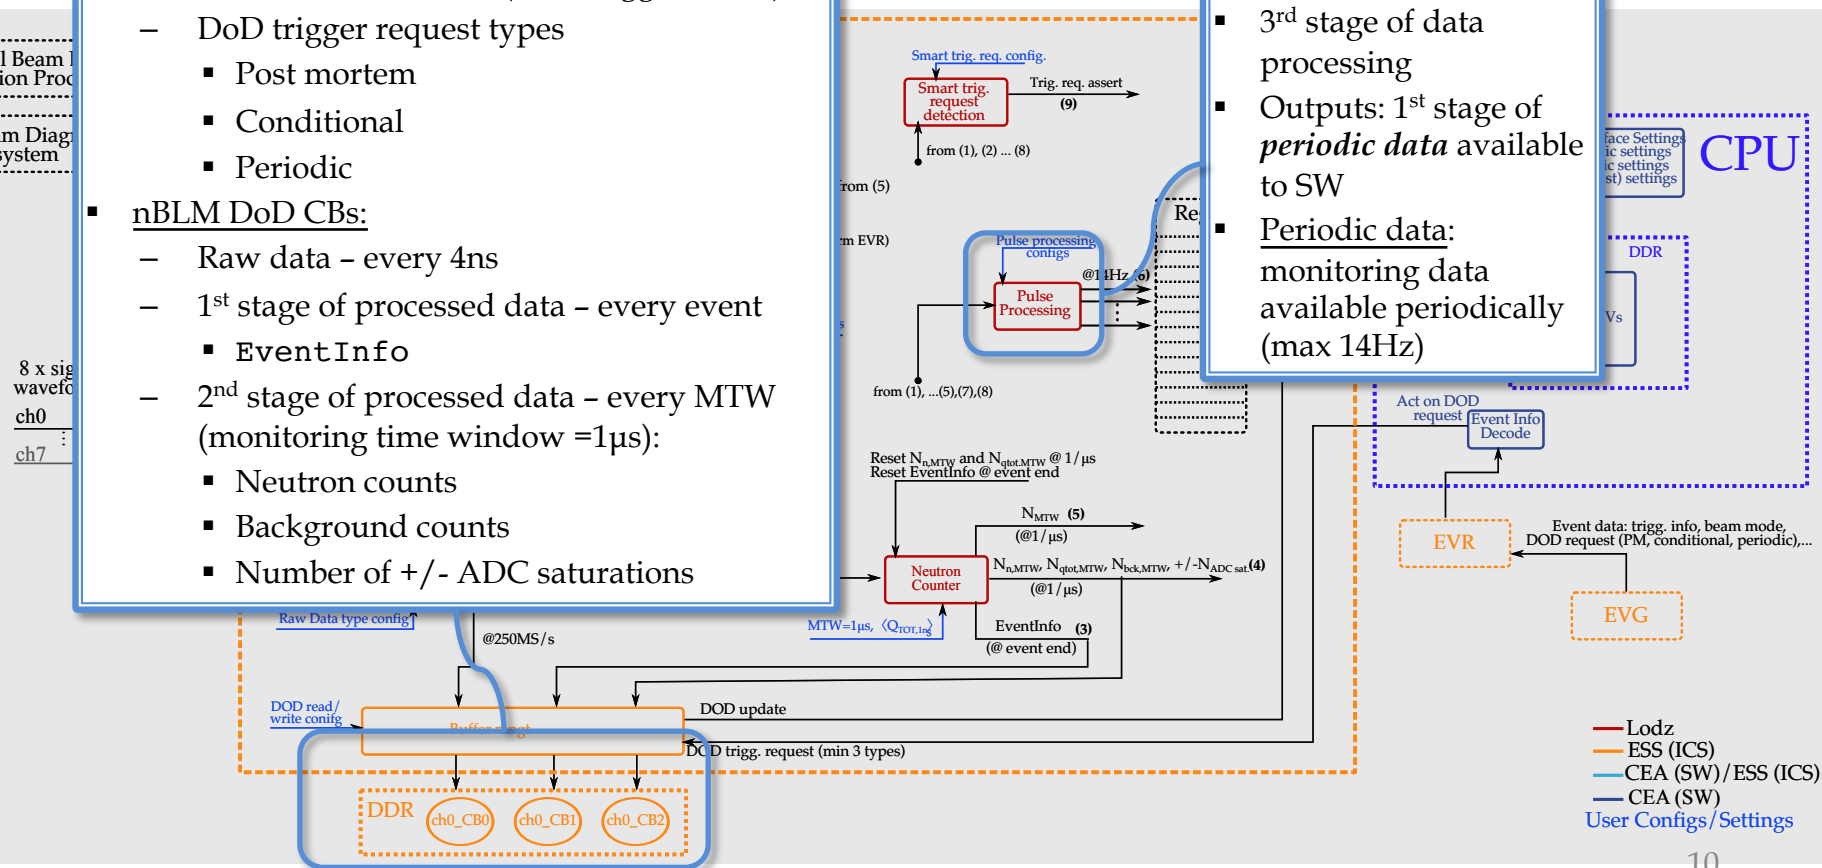

# nBLM FW functionality

## Buffering of Data-On-Demand (DoD)

- DoD data:
  - available on demand (DoD trigger assert)
  - DoD trigger request types
    - Post mortem
    - Conditional
    - Periodic
- nBLM DoD CBs:
  - Raw data - every 4ns
  - 1<sup>st</sup> stage of processed data - every event
    - EventInfo
  - 2<sup>nd</sup> stage of processed data - every MTW (monitoring time window =1 $\mu$ s):
    - Neutron counts
    - Background counts
    - Number of +/- ADC saturations

## Pulse processing

- 3<sup>rd</sup> stage of data processing
- Outputs: 1<sup>st</sup> stage of *periodic data* available to SW
- Periodic data: monitoring data available periodically (max 14Hz)

# nBLM FW functionality

## Low Latency Link block

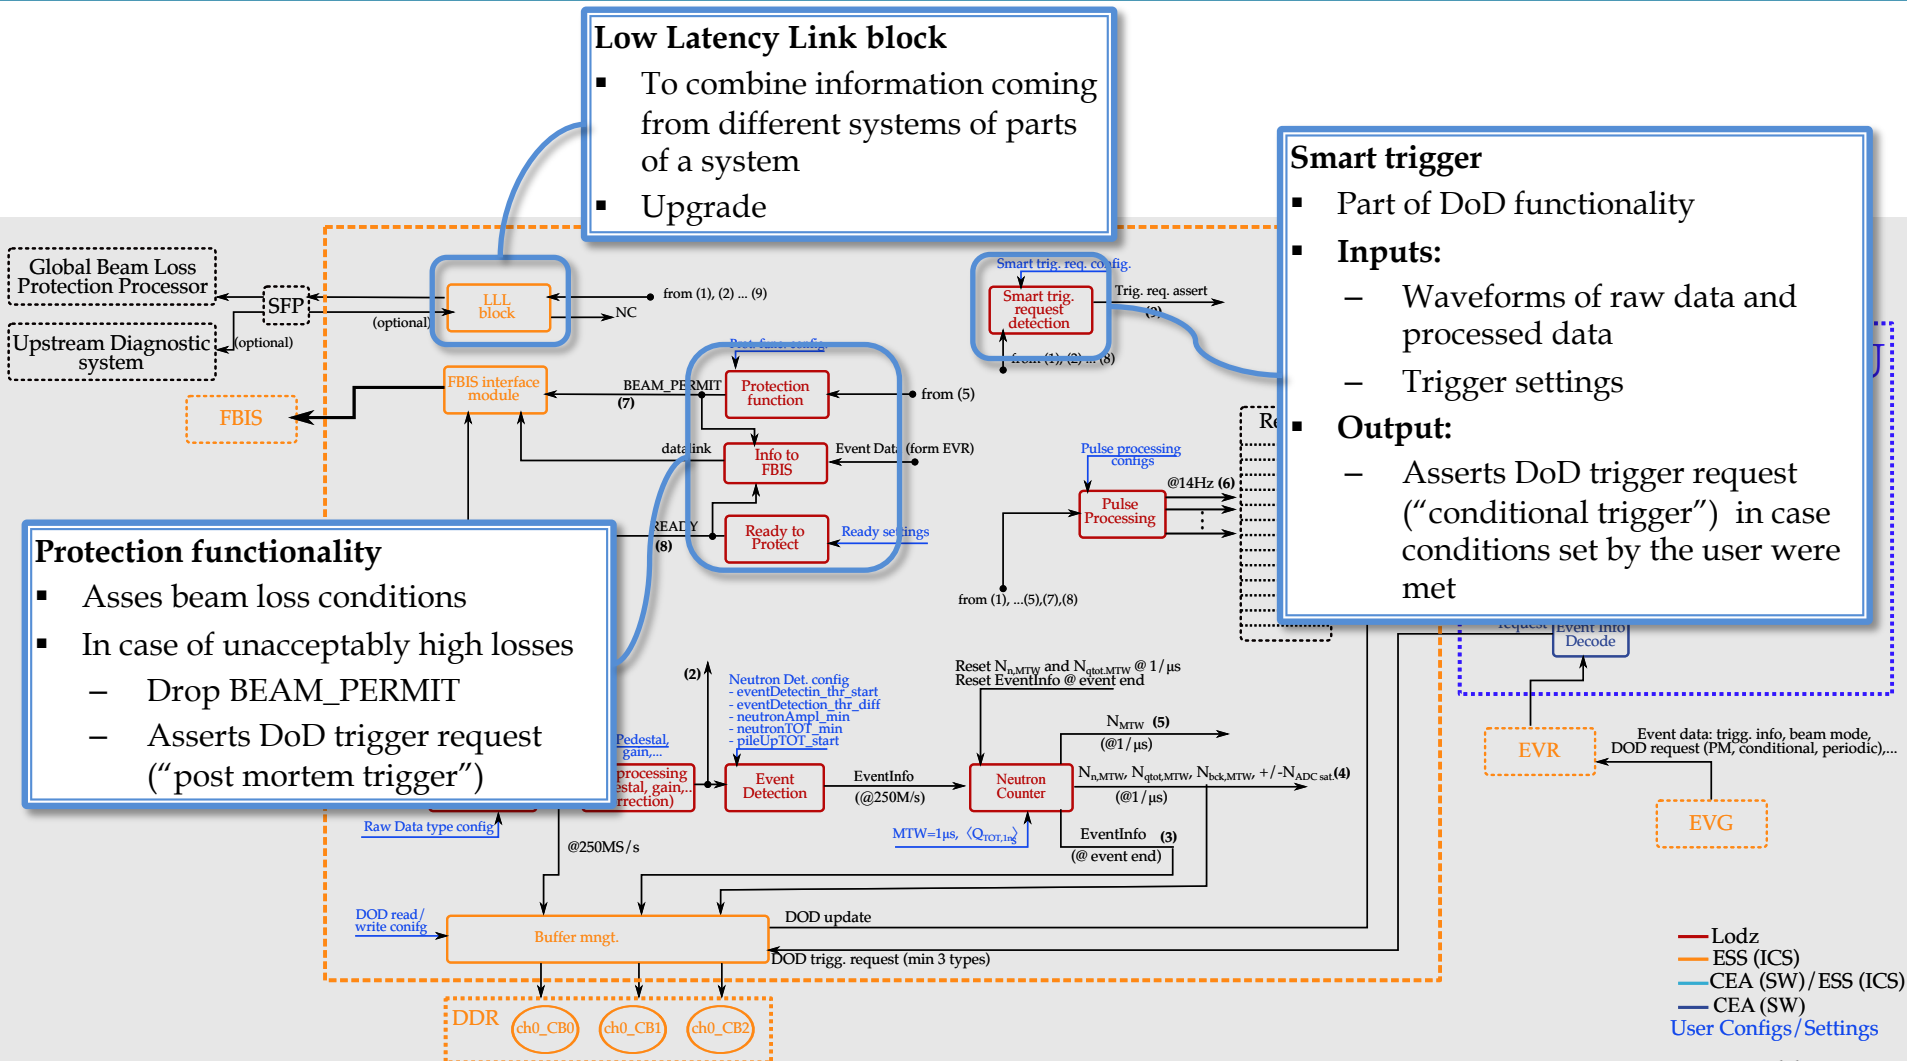

- To combine information coming from different systems of parts of a system
- Upgrade

## Smart trigger

- Part of DoD functionality
- Inputs:**
  - Waveforms of raw data and processed data
  - Trigger settings
- Output:**
  - Asserts DoD trigger request ("conditional trigger") in case conditions set by the user were met

## Protection functionality

- Asses beam loss conditions
- In case of unacceptably high losses
  - Drop BEAM\_PERMIT
  - Asserts DoD trigger request ("post mortem trigger")

- Lodz
- ESS (ICS)
- CEA (SW)/ESS (ICS)
- CEA (SW)
- User Configs/Settings

# nBLM: neutron detection algo

## What do the neutron detection related blocks provide?

- **Number of neutrons** reported after every MTW -  $N_{MTW}$ 
  - Is calculated as a sum of a pair of numbers, representing the counts inside MTW calculated by the two different methods.
  - At the end of each MTW:
    - $N_{MTW}$  is stored in the CB2 and
    - $N_{MTW}$  is reset at the end of every MTW.
  - Additional data stored in CB2:
    - Number of pos. ADC saturations
    - Number of neg. ADC saturations
    - Background counts
- **EventInfo** for each “interesting event”
  - The structure contains information about the event (Q, TOT, rise time, time stamp,...)
  - The structure is stored in the circular buffer CB1 and
  - Reset at the end of each “interesting event”.

### *MTW (Monitoring Time Window):*

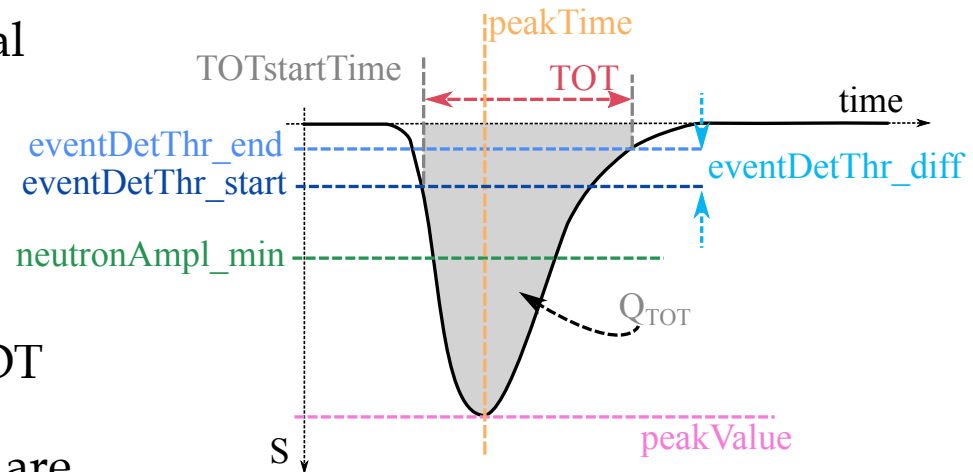

- *Time window in which the neutron counts are measured/reported*
- *Currently set to 1us (250 samples).*

# nBLM: neutron detection algo

## EventInfo structure

- TOT - event Time Over Threshold
- Q\_TOT - charge inside the TOT window
- peakValue - amplitude (min signal inside TOT window)
- TOTstartTime
- peakTime
- peakValid - true if condition on amplitude for single neutron is met
- TOTvalid - true if condition on TOT for single neutron is met
- pileUp - true if pile up conditions are met
- MTWindx - index of the MTW where event started
- isTruncated - true if event 1. part of a split signal
- isPart2 - true if event 2. part of a split signal

# nBLM: neutron detection algo

## Basic idea (CEA):

- Detect “interesting events”
  - Identify **single neutrons**
    - *TOT within a certain range*
    - *Amplitude below a certain limit*
  - Identify **pile-up** events
    - *Amplitude below the same limit as for single neutron*
    - *TOT above the upper limit for single neutron*
- Use either of 2 methods for neutron counting for each neutron event:
  - Single neutron counting method
    - for single neutron events: count events
  - Charge method:
    - for pile-up events: calculate counts from charge

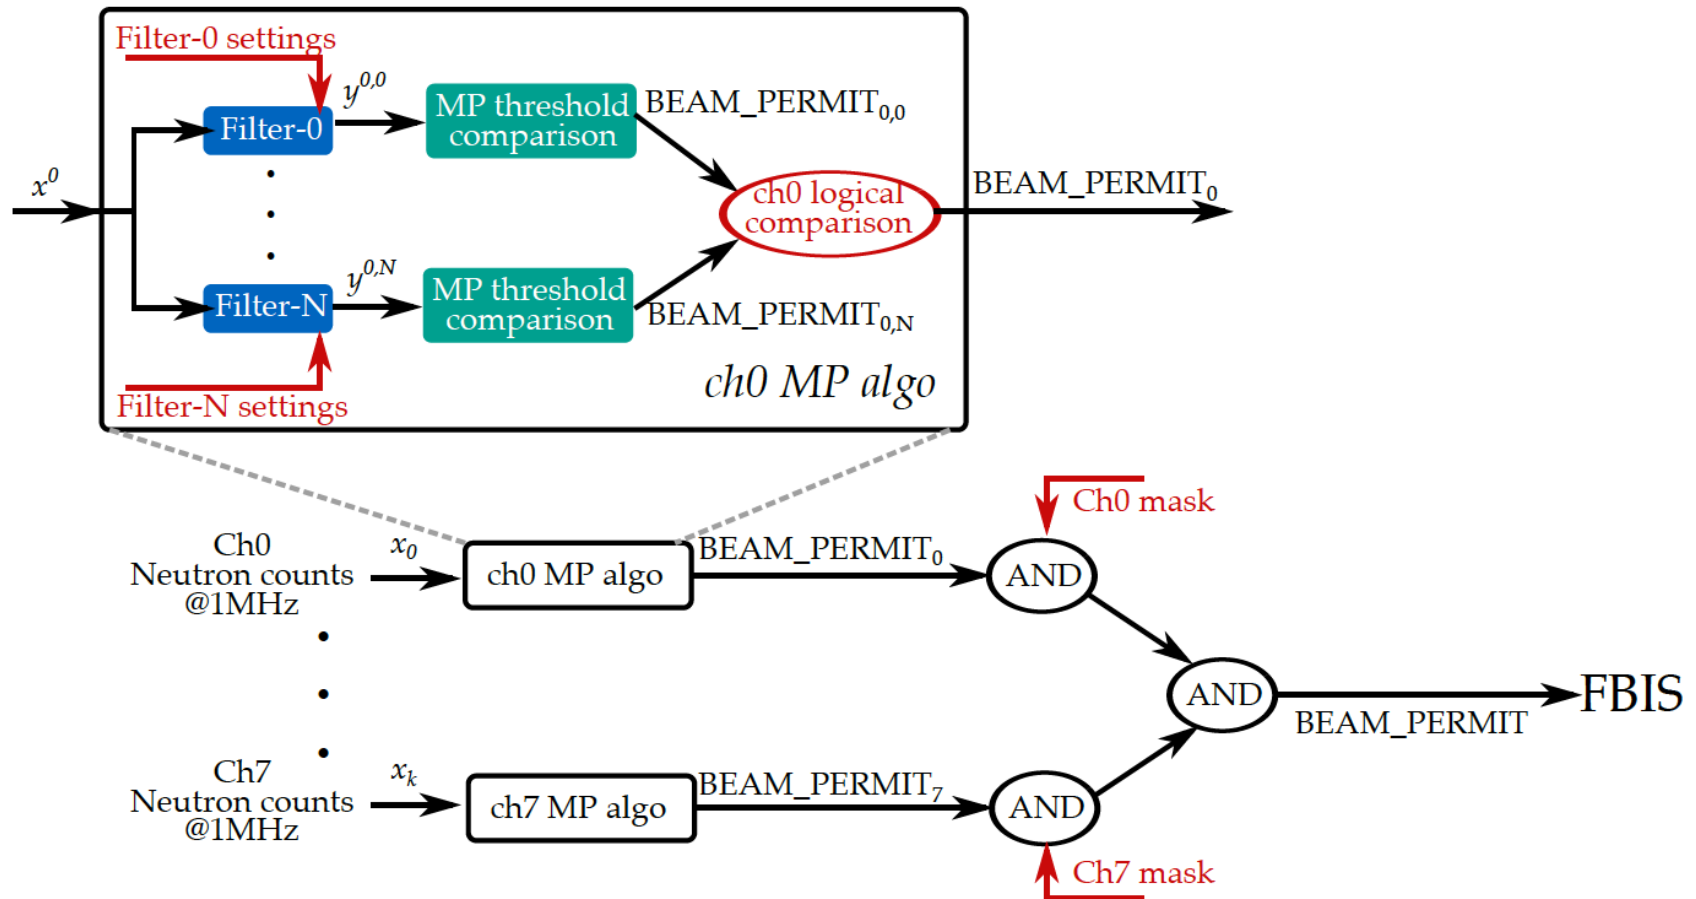

## nBLM data processing (by ESS):

- Basic idea applied to real time processing and MTW framing of counts/events.
- Requirement: algo must provide information (neutron counts) without unnecessary delays.
- Both nBLM-F and -S have the same neutron algo running (different settings)

# Protection algorithm

1 BEAM\_PERMIT per AMC propagated to FBIS

# Protection algorithm

- To avoid spurious BEAM\_PERMIT drops
  - Filtering measurements on each channel
  - Coincidences - upgrade (functioning LLL needed)
  
- Foreseen filter types
  - Relaxation filter (baseline)
  - Moving average (consistent with BCM)
  - Simple average (consistent with BCM)
  - X/Y algo

## Relaxation filter

- 1<sup>st</sup> order IIR filter (with feedback)
- Output = weighted sum of old output  $y_{k-1}$  and new input value  $x_k$

$$y_k = \lambda y_{k-1} + (1 - \lambda)x_k$$

- $\lambda \rightarrow 1$ :
  - Forgets little
  - Comparable to moving average with large number of points

# Protection algorithm

## Moving average

- Calculate local average over the last time window  $t_{MA}$  (last  $n$  input points  $x_k$ )

$$y_k = \frac{1}{n} \sum_{l=0}^{n-1} x_{k-l}$$

- Increasing  $n$ : smoothing improved, delay between output and input increased.

# Protection algorithm

## Simple average

- Calculation carried out with a fresh set of values on each calculation restart.

## X/Y algo

- Takes Y last number of inputs  $x_k$
- If X out of them are above the MP threshold,  $BEAM\_PERMIT_{c,X/Y}=1$
- Input  $x$ : neutron counts @ 1MHz
- Output  $y$ :  $BEAM\_PERMIT_{c,X/Y}$

# Protection algorithm

## **5 filter instances to be tested during commissioning:**

- 2 time constants for moving average ( $t_{MA,1} \sim 1\mu\text{s}$ ,  $t_{MA,2} \sim 100\mu\text{s}$ )
- Simple average over beam pulse ( $\sim 3\text{ms}$ ).
- Relaxation filter.
- X/Y algo.

## **Further developments**

- Foreseen based on beam commission experience and simulations
- Plan to co-develop protection functions across the BI systems providing loss information

# 1<sup>st</sup> nBLM DAQ test (LINAC4)

- Linac4 (CERN) – realistic environment (close to ESS DTL)
- nBLM-F detector installed at DTL1-DTL2 intertank region (12MeV H<sup>-</sup>)
- 2 days available for tests with ESS DAQ in Dec. 2018
  - Controlled losses: readout split between ESS DAQ and scope (or CERN readout) – 1<sup>st</sup> day
  - Normal operation: only ESS DAQ connected – 2<sup>nd</sup> day

# 1<sup>st</sup> nBLM DAQ test (LINAC4)

- IFC1410 based
  - no external triggering available (working fw version, Lodz support to extract the data)
  - no useful data collected during controlled losses (2 x 10min just after DAQ installation)...
    - Need to set proper settings before meaningful processed data can be collected – no time to do that, therefore decide to collect both raw and processed data
    - Collected waveform shorter (~0.75s) than configured (2.5s) since processed data buffers were enabled.
    - A few files had zeros in collected data (reboot helped)
    - Unstable platform – frequent reboots needed
  - All useful data collected during “normal operation”
- Struck based
  - No external trigger
  - But 8s of raw data collected ~ few minutes.
  - All collected during “normal operation”

# 1<sup>st</sup> nBLM DAQ test (LINAC4)

## Collected data - used in analysis (last day)

- IFC1410
  - ~8 x 2s of raw data
  - ~8h of *EventInfo* data
- Stuck based
  - 5 x 8s of raw data collected.
- Detector settings: the same in all runs analysed here
- Results
  - More details in report for CDR3 (I. Dolenc Kittelmann, “*Preliminary results of the nBLM DAQ test at Linac4*”)

# 1<sup>st</sup> nBLM DAQ test (LINAC4)

## IFC1410 raw data with subtracted pedestal

- Plot below: signal waveform with visible pulse (mostly gammas) during run7
- Observation: "Charging" and "discharging" structures with 5.5 -6 us distance always surrounding a pulse
- pulsed magnets?

# 1<sup>st</sup> nBLM DAQ test (LINAC4)

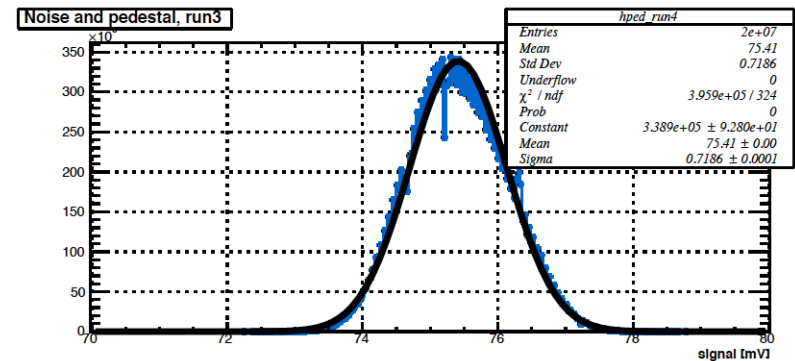

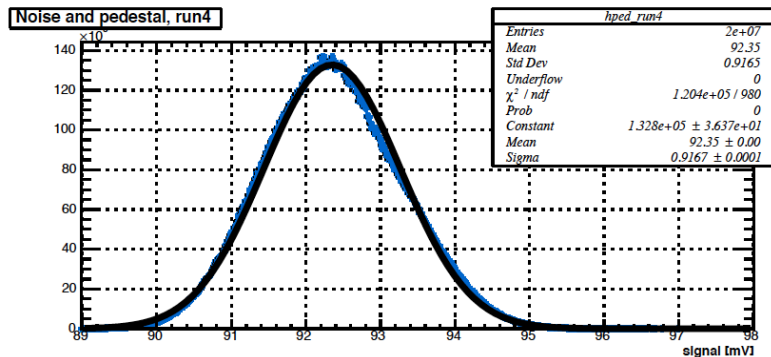

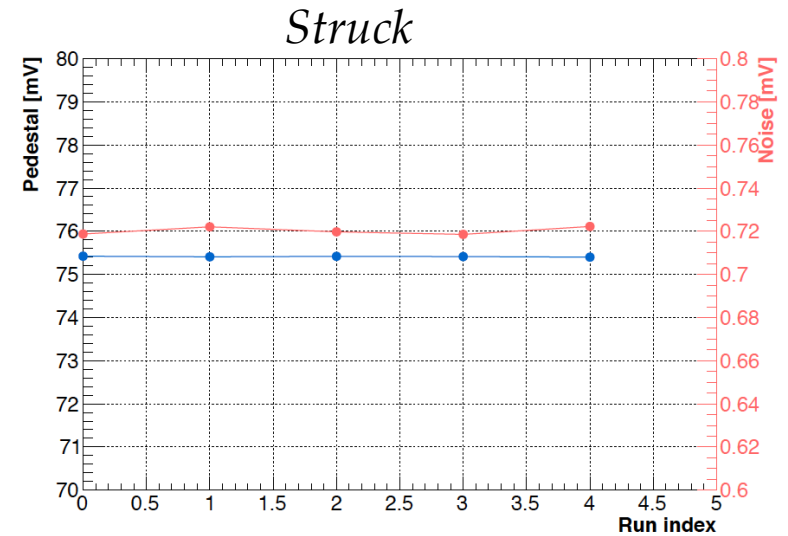

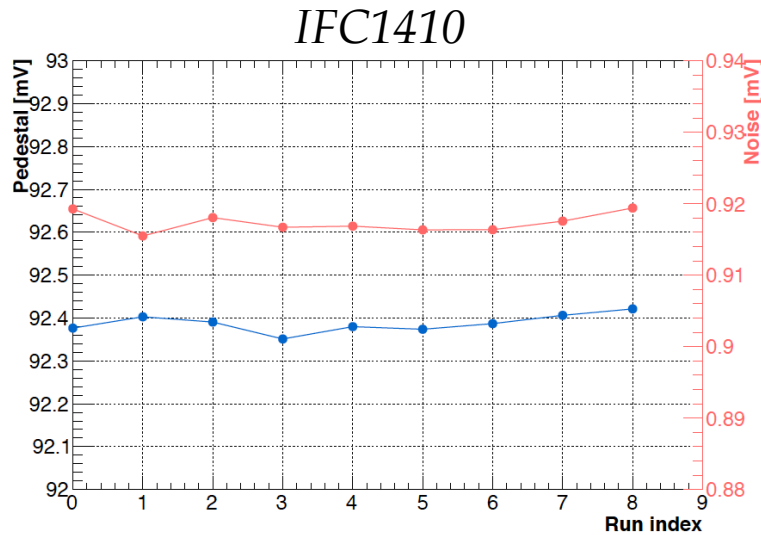

## Raw data with subtracted pedestal

- Plots on the left: plot from the previous slide zoomed to
  - The RF pulse time window (top plot)
  - Last part of the RF time window (mid plot)
  - Last gamma signal in the RF time window (bottom plot)
- Observation:  $\sim 37\text{kHz}$  pickup

# Raw data - ifc1410 vs Struck: noise & pedestal

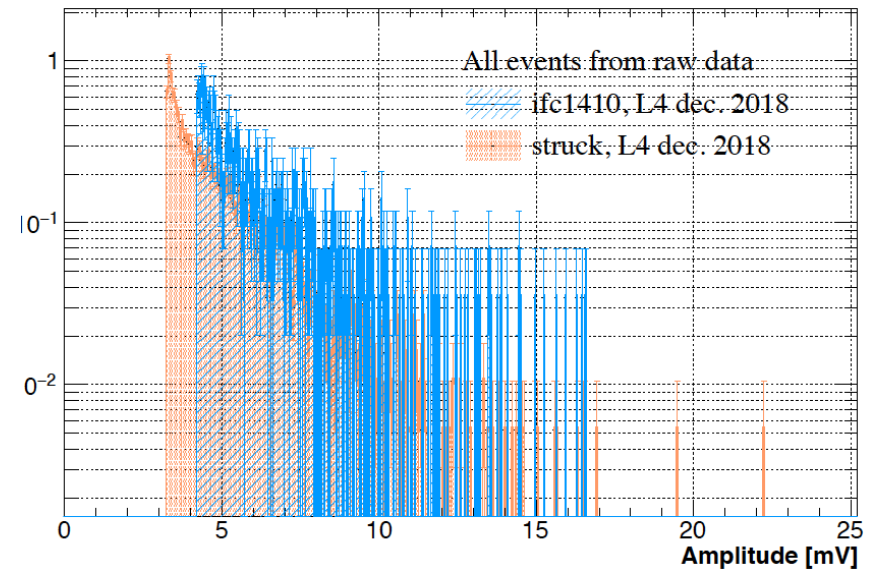

## Noise & pedestal

# Raw data - IFC1410 vs Struck: TOT & Amplitude

## Distributions from raw data - IFC1410 (blue) and Struck (orange) data

- Plots below:
  - TOT**: time window between events start and end
  - Amplitude**: minimum signal in the TOT window
  - Event detection thrs**: struck settings = settings for ifc1410 scaled to give the same Threshold/noise
- Amplitude distribution:
  - 1<sup>st</sup> slop: spikes/noise, 2<sup>nd</sup> slope: gammas
  - Neutrons: after 15mV?, not enough statistics
- IFC1410 & Struck data consistent?
  - TOT - yes
  - Amplitude: yes? not enough statistics for IFC1410

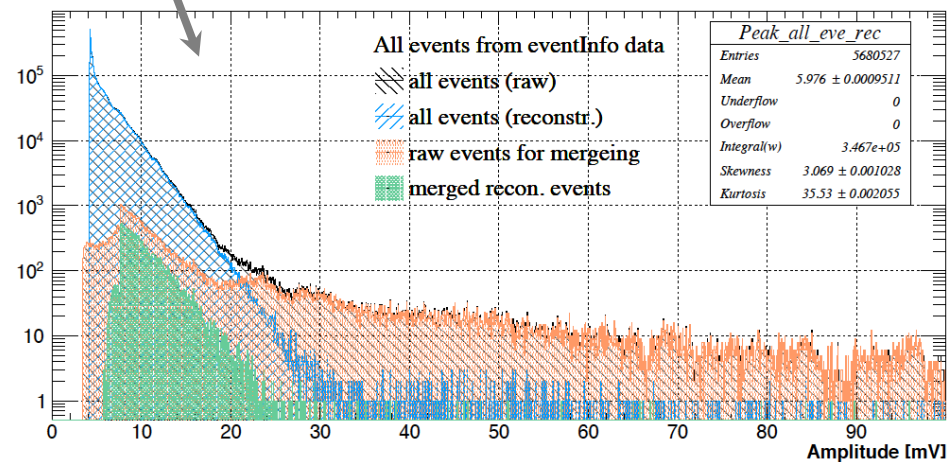

# IFC1410: *EventInfo* data

## Note:

- Online event detection: framing & splitting events
- Offline analysis: event reconstruction required – **blue histo**
- “Raw *EventInfo* data” (as collected) – black histo

## Amplitude:

- Neutrons above  $\sim 30\text{mV}$ ? – consistent with scope results (CEA)

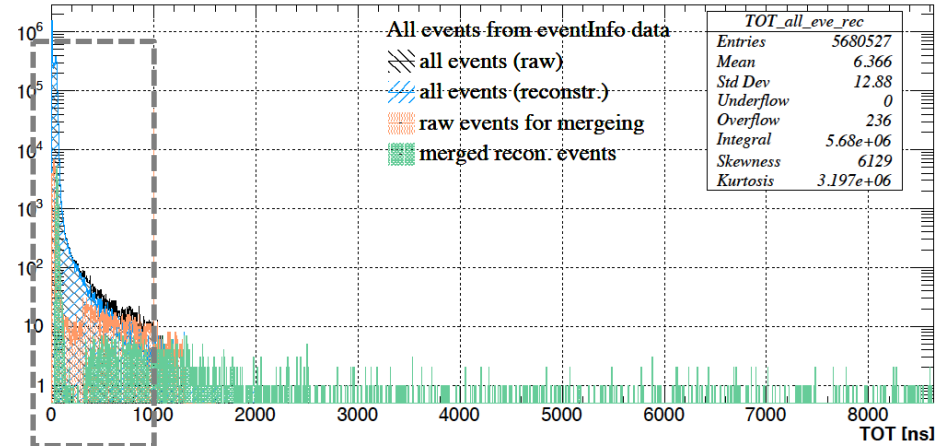

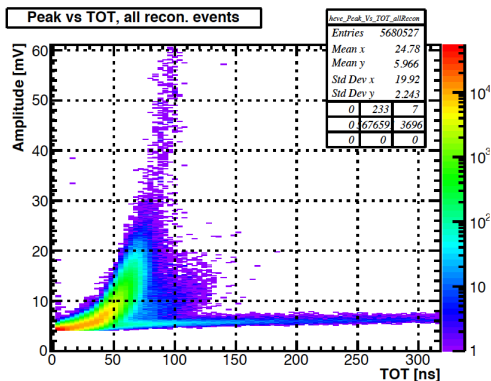

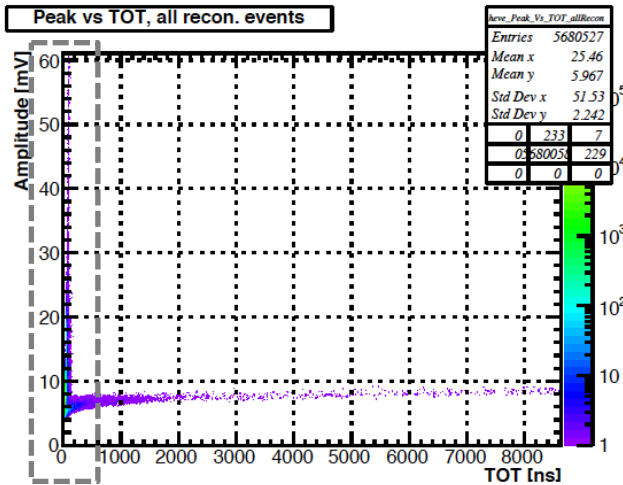

# IFC1410 EventInfo data

## TOT:

- Events extending over several  $\mu$ s present - baseline/pedestal shifts
- With proper algo settings: amplitude cut enough to distinguish between gammas and single neutrons

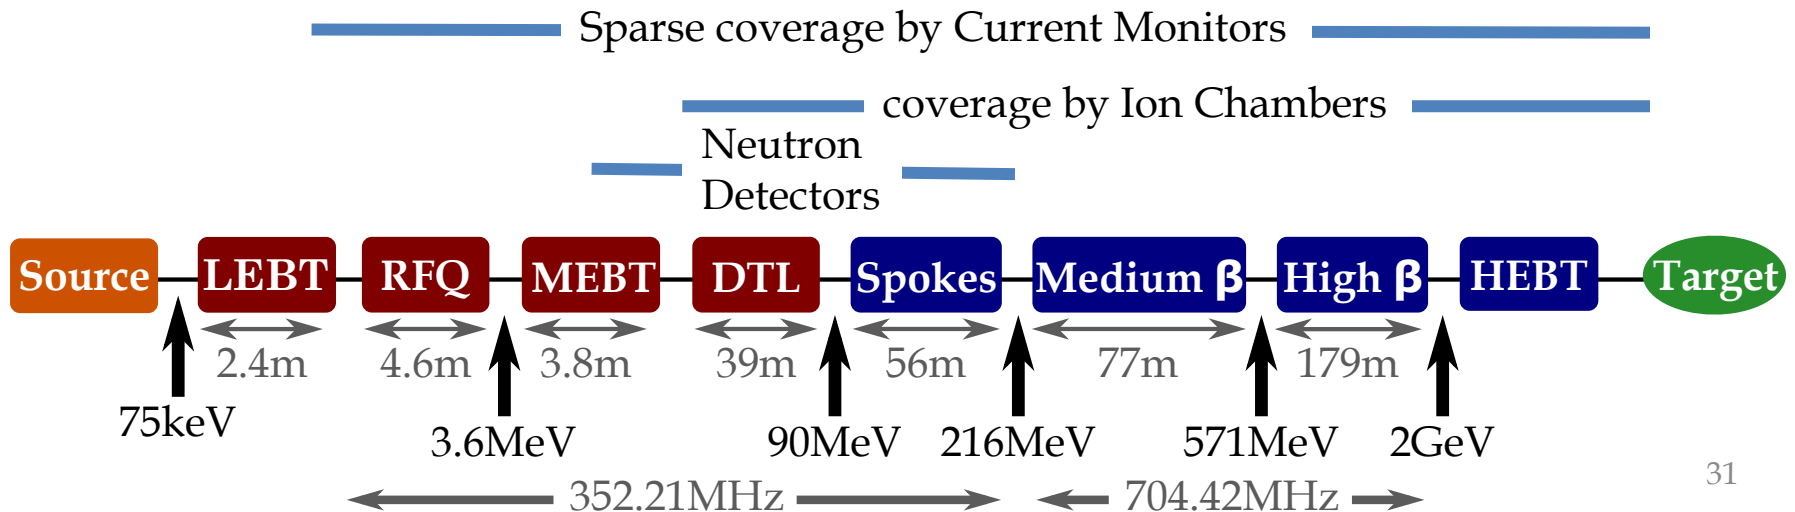

*Back up  
material*

# ESS Beam Loss diagnostic tools

(from T. Shea)

- **Total beam loss**, microsecond measurement latency required for protection
  - BCM, icBLM (saturation, nBLM (current mode) → Interlock; Threshold/derivative term for fast protection
- **> 1.6 milliamp lost for up to 200  $\mu$ s**
  - BCM, icBLM, nBLM → Interlock; Damage model for protection
- **$\sim \mu$ C lost over 200  $\mu$ s to many seconds** (diffusion time)
  - icBLM, nBLM → Interlock; Damage model for protection
- **$\sim$  “1 Watt/meter” radiation dose management**
  - icBLM, nBLM → alarm based on dose/activation plan

# ESS BLM: Response time

- Required response time set in the past:
  - NC linac (MEBT-DTL):  $\sim 5 \mu\text{s}$ .
  - SC linac:  $\sim 10 \mu\text{s}$ .
  - Numbers based on a simplified melting time calculations, where a block of material (copper or stainless steel) is hit by a beam of protons with a uniform profile under perpendicular incidence angle, no cooling considered [9].
- Numbers re-checked with a Gaussian beam and update beam parameters:
  - **NC linac:** calculated melting time values of  $3\text{-}4\mu\text{s}$  imply even stronger demands on the response time (confirmed with a MC simulation as well).
  - **SC linac:** the  $10\mu\text{s}$  requirement for response time fits well with the results of this calculations.However: other damage mechanisms may mandate even shorter response time SCL (discussed further).

# ESS BLM: detector layout (MEBT-MB)

## nBLM-F vs. nBLM-S

- Majority of the linac: F and S placed separately in an alternating fashion
- At certain locations: a pair of F & S device

## Normal conducting linac (NCL):

- nBLM:
  - MEBT: 4 devices (nBLM)
  - DTL:  $\sim 1$  device / 1m
- icBLM:
  - DTL: 1device/tank

## Superconducting linac (SCL):

- nBLM
  - Spoke: 1 device / 2m
  - Sparsely located in other parts of SCL
- icBLM:
  - 3/quad pairs
  - 1/cryo

# ESS BLM: detector layout (HB – end)

## nBLM-F vs. nBLM-S

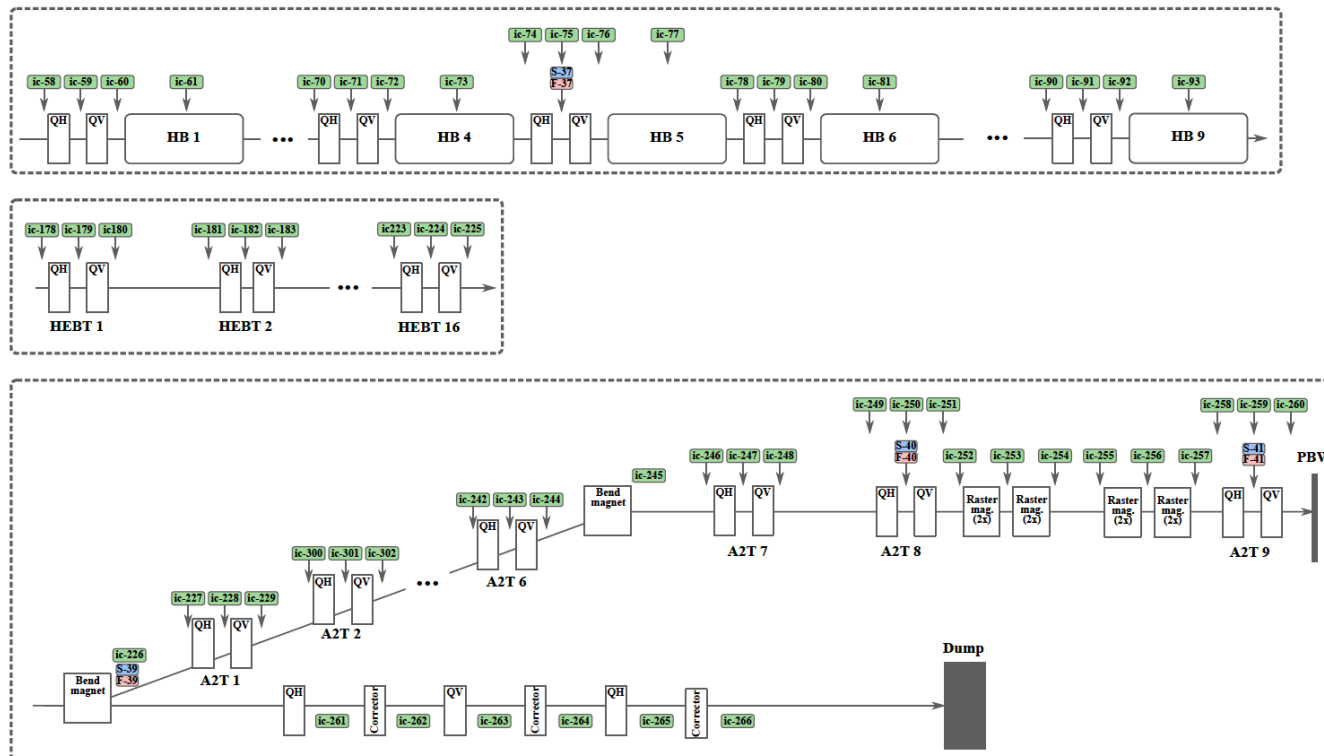

- Majority of the linac: F and S placed separately in an alternating fashion
- At certain locations: a pair of F & S device

## Normal conducting linac (NCL):

- nBLM:
  - MEBT: 4 devices (nBLM)
  - DTL: ~ 1 device / 1m
- icBLM:
  - DTL: 1device/tank

## Superconducting linac (SCL):

- nBLM
  - Spoke: 1 device / 2m
  - Sparsely located in other parts of SCL
- icBLM:
  - 3/quad pairs
  - 1/cryo

# nBLM: Detectors (1)

## nBLM detectors:

- 2 types,
- depending on location placed separately or back-to-back (detector unit)
- **1<sup>st</sup> module (slow losses): nBLM-S**
  - Capable of monitoring low fluxes ( $\sim$ few  $n\text{ cm}^{-2}\text{s}^{-1}$ ).
  - Response time:  $\sim 200\mu\text{s}$  ( $\sim 10\%$  events detected in  $4\mu\text{s}$ ).
  - Polyethylene ( $\sim 4\text{cm}$ ): moderator to thermalize the incoming fast n.
  - $\text{B}_4\text{C}$  layer (deposited on the Al surrounding the gas chamber) to capture thermalized n -  $(n,\alpha)$   $^{10}\text{B}$  reaction ( $\alpha$  with fixed energy of  $1.4\text{MeV}$ ).
  - Borated rubber to eliminate background thermal  $n$ .
  - Efficiency: few  $10^{-2}$  ( $1\text{eV} < E_n < \text{few } 10\text{MeV}$ )
  - Solid angle:  $4\pi$

- Al chamber
- He (90%),  $\text{CO}_2$  gas
- Borated rubber ( $\sim 1\text{mm}$ )
- Polyethylene ( $\sim 4\text{cm}$ )
- $\text{B}_4\text{C}$  deposited on Al
- Micromegas detector

# nBLM: Detectors (2)

## nBLM detectors:

- **2<sup>nd</sup> module (fast losses): nBLM-F**
  - appropriate for high fluxes of fast  $n$ , coming from the front ( $\sim$ few  $0.01 n \text{ cm}^{-2}\text{s}^{-1}$ ).
  - Polypropylene (deposited on Al foil at the entrance window) for  $n$  conversion to  $p$  recoils ( $\sim$  few mm) through  $n$  elastic scattering on H atoms (continuous distribution of recoiled  $p$  energies).
  - Cross-section threshold:  $E_n \sim 0.5 \text{ MeV}$ .
  - Efficiency: 10-100 times lower than for nBLM-S ( $10^{-5}$ - $10^{-3}$  for  $E_n = \sim 0.5 \text{ MeV} - 10 \text{ MeV}$ )
  - Solid angle:  $2\pi$
  - Response time:  $\sim 10 \text{ ns}$

- Al chamber
- He (90%), CO<sub>2</sub> gas
- Plastic deposited on Al (mylar, polypropylene)
- Micromegas detector

# nBLM: Signals

- Typical neutron signal:
  - 30-50ns rise time
  - 100-200ns signal length
  - Amplitude
    - ~Constant for S
    - Continuous distribution for F
- nBLM originally planned to operate in **counting mode**
- MC simulations: up to GHz rates expected in case of complete loss.

Rates		
	1% 1W/m	Complete beam loss (rate in 1 <sup>st</sup> $\mu$ s)
Slow	0.1 – 68 kHz	10MHz – 60 GHz
Fast	1 – 400 Hz	2-700 MHz

- Minimum response time for the system to drop the BEAM\_PRMIT:  $\sim 5\mu$ s
- If counts are monitored in  $1\mu$ s time window: pile-up when  $\geq 6$  counts (“neutron events”)  $\Rightarrow$  transition to **current mode**.
- The FPGA neutron detection algo. is foreseen to automatically transition to current mode (monitoring both TOT and Q).

# nBLM electronics layout: signal

## 3 groups of detectors

- To limit the situations with larger parts of the system un-operational
- MEBT - Spoke: signal electronics for each group placed in separate racks
  - Group1: Odd pairs of S & F detectors
  - Group1: Even pairs of S & F detectors
- MB - A2T: Group3

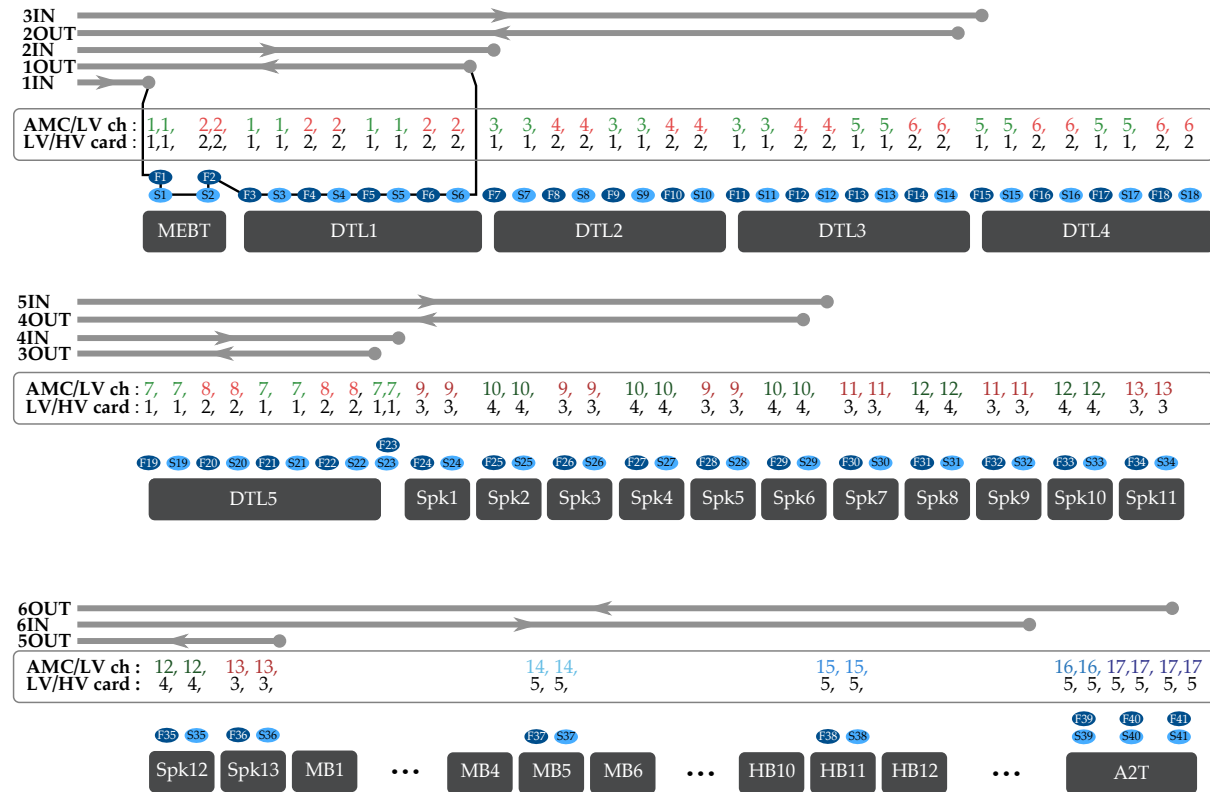

# nBLM electronics layout: signal

Estimated signal cable lengths 40 – 90m

# nBLM electronics layout: HV, LV

- Same crate for LV and HV PS
- 2 HV lines per detector
- Each LV channel used to power several detector modules
- 2 crates along the linac
  - Separation in HV and LV connections between group 1 and 2 not possible down to the rack level
  - A set of detector modules
    - connected to an AMC/FMC has FEE powered by the same LV channel
    - with signal connected to the same rack has all HV cables connected to the same HV module

# nBLM electronics layout

Rack	Detector count	AMC count	Crate count	Detectors per AMC	AMC tag	Spare cables per rack

**Table 4:** Summary of the nBLM system HV connections. The column marked as “Det. per HV card” indicates the number of detectors powered by each HV card. Note that each a detector needs two HV connections, one for mesh (M) and one for drift (D). The colours mark different detector groups as discussed in the text and shown on figure 6.

# nBLM: neutron detection algo

## “Interesting Event”

- Basic rule:
  - Starts when signal falls below start event threshold.
  - Ends when signal exceeds the end event threshold.
- Exceptions when signal extends over MTW edge
  - Split signal in 2 events if:
    - At the MTW edge the signal already qualifies as a single neutron.
    - Event too long (longer max TOT for a single neutron)
  - Otherwise end the event when signal exceeds end event threshold in the following MTW.

# nBLM: neutron detection algo

## “Interesting Event” types

- Single neutron
- Neutron pile up
- Background (gamma or other)
- Spike/noise, spark

# nBLM: neutron detection algo

## Neutron identification

- Single neutron
  - TOT: within limits
  - Amplitude: below the threshold
- Pile up neutrons
  - TOT larger than for single neutron
  - Amplitude: below the threshold

$$\text{pileUpTOT\_start} > \text{TOT}_j \geq \text{neutronTOT\_min}$$

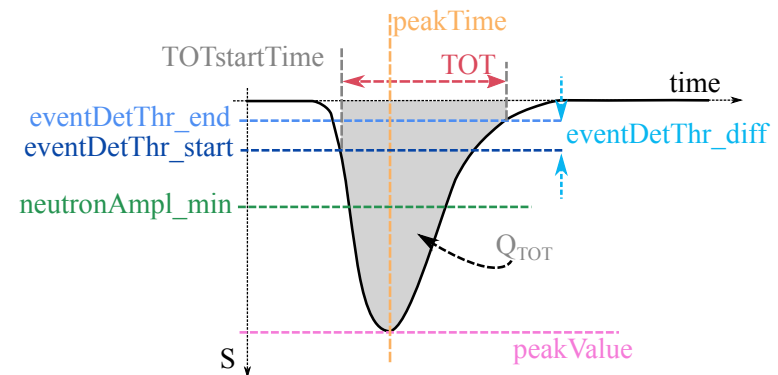

$$\text{peakValue}_j \leq \text{neutronAmpl\_min}$$

$$\text{TOT}_j \geq \text{pileUpTOT\_start}$$

$$\text{peakValue}_j \leq \text{neutronAmpl\_min}$$

## Background identification

- Valuable for
  - Comparison with icBLM data and/or
  - Crosscheck that algo or detector settings are ok
- Initial version:
  - TOT above the limit for single neutron
  - Amplitude above single neutron limit

$$\text{TOT}_j \geq \text{neutronTOT\_min}$$

$$\text{peakValue}_j > \text{neutronAmpl\_min}$$

# nBLM: neutron detection algo

## Neutron Counts per MTW:

$$N_{MTW,i} = N_{n;MTW,i} + N_{qtot;MTW,i} = \sum_{j=1}^{n_{eve;MTW,i}} (N_{n,j} + N_{qtot,j})$$

Number of single neutron events with i-th MTW  
(Single neutron counting method)

Number of neutrons within i-th MTW calculated through **charge method**

- For pile up (or split) events:

$$N_{qtot,j} = \frac{Q_{TOTj}}{\langle Q_{TOT1n} \rangle}$$

- Else:

$$N_{qtot,j} = 0$$

# nBLM: neutron detection algo

## Neutron detection related blocks

- “Event Detection”
  - Detects start of an “interesting event”
  - Updates EvenInfo every 4ns
- “Neutron counter”
  - Ends event and resets EventInfo
  - Sums and resets neutron counts at the end of each MTW
